Unsaturated palm oil fatty alcohols

Field of the invention

The invention relates to unsaturated fatty alcohols which are obtained by fractionating palm oil fatty acid methyl esters, and then hydrogenating the fraction of unsaturated long-chain methyl esters, and to a process for the preparation of these fatty alcohols.

10 Prior art

Unsaturated fatty alcohols are important intermediates for a large number of products of the chemical industry, such as, for example, for the preparation of surfactants and skincare products. A review on this topic can be found, for example, by U. Ploog et al. in **Seifen-Öle-Fette-Wachse [Soaps-Oils-Fats-Waxes]** 109, 225 (1983). They are prepared from more or less unsaturated fatty acid methyl esters which can be hydrogenated, for example, in the presence of chromium- or zinc-containing mixed catalysts [**Ullmann's Encyclopedia of Industrial Chemistry, Verlag Chemie, Weinheim, 4th Edition, Vol. 11, p. 436 ff**]. The prior art is a large-scale process, as has hitherto also been carried out by the applicant, according to which animal fats and oils are used, and the unsaturated fatty alcohols produced after the hydrogenation are distilled at a still temperature of e.g. 220 to 250°C and a reduced pressure of from 1 to 20 mbar - measured at the top of the column. Since the preparation of unsaturated fatty alcohols is associated with high costs, distillation has been carried out with as low a raw material loss as possible. In fact, in this way, it was possible to achieve a yield of about 90% of theory, and correspondingly a loss of 10%, although the products exhibited a marked intrinsic odor. A further disadvantage is that the fatty alcohols of the prior art have unsatisfactory storage and low-temperature behavior.

For application reasons, unsaturated fatty alcohols having iodine numbers of from 50 to 80 are particularly preferred since these have a solidification point which is favorable for use in cosmetic products. Unsaturated fatty alcohols having iodine numbers in the abovementioned range are currently largely based on animal raw materials. The desired iodine number range is set by blending different products having differing iodine number ranges. Adjustment of the iodine number range by distillative methods is not possible since the iodine number or iodine number range of animal-based fatty acids or fatty alcohols remains virtually constant during fractionation. However, animal fats have the disadvantage that they have a very heterogeneous structure. For example, animal fats contain nitrogen-containing compounds, such as amides or steroids, such as, for example, cholesterol, which are directly or indirectly responsible for the abovementioned unpleasant odor of the products. The nitrogen-containing compounds can become involved in secondary reactions, which impairs product stability, in particular oxidation stability, and leads to discolored products. In addition, because of the continuing BSE debate, products which are prepared using beef tallow are viewed extremely critically by the consumer. In the cosmetics market, there is therefore a continuous need for ever purer raw materials of ever higher quality, a demand which can usually only be met by ever more complex industrial processes and additional purification steps. In the case of unsaturated fatty alcohols, there is, in particular, the need for products having improved color and odor quality and a more advantageous low-temperature behavior. Added to this is the fact that in recent years consumer behavior has changed to the effect that consumers place very great value on purely vegetable products. The known vegetable fatty alcohols have iodine numbers in the range below 20 or very high iodine numbers above 100.

The object of the present invention was consequently to provide unsaturated fatty alcohols based on palm oil which have iodine numbers in the range from 65 to 85 and, compared with animal-based 30 unsaturated fatty alcohols, have greater oxidation stability and comparable or better low-temperature behavior. The aim was also to obtain extremely pure coupled products.

The invention provides unsaturated palm oil fatty alcohols having an iodine number in the range from 65 to 85, which essentially comprise unsaturated fatty alcohols and mixtures of saturated fatty alcohols of the formula (I)

R¹OH

(I)

in which R¹ is a saturated or unsaturated, linear or
5 branched alkyl radical having 14 to 20 carbon atoms,
obtainable by

- (a) fractionating palm oil fatty acid methyl esters
into a predominantly saturated C₁₆ distillate and a
predominantly unsaturated C_{16/18} bottom product, and
- 10 (b) hydrogenating the bottom product with retention of
the double bonds to give the corresponding
alcohols.

Surprisingly, we have found that, by the
process according to the invention, it is now possible
15 for the first time to obtain unsaturated fatty
alcohols, even those based on palm oil, in the iodine
number range from 65 to 85 and which have good color
and oxidation stability and excellent low-temperature
behavior; additionally, the products are virtually
20 odorless. A further advantage is that a very pure
palmitic acid methyl ester fraction is obtained as an
intermediate, which can be further processed
separately.

The invention further provides a process for
25 the preparation of unsaturated palm oil fatty alcohols
having an iodine number in the range from 65 to 85,
which essentially comprise unsaturated fatty alcohols
and mixtures of saturated fatty alcohols of formula (I)

30 R¹OH

(I)

in which R¹ is a saturated or unsaturated, linear or
branched alkyl radical having 14 to 20 carbon atoms, in
which

- 35 (a) palm oil fatty acid methyl esters are fractionated
into a predominantly saturated C₁₆ distillate and a
predominantly unsaturated C_{16/18} bottom product, and

(b) the bottom product is hydrogenated with retention of the double bonds to give the corresponding alcohols.

Fractionation

5 The fractionation of the palm oil fatty acid methyl esters can be carried out batchwise or continuously at reduced pressure. Heating can, for example, be by means of superheated steam, a still temperature of e.g. 220 to 250°C normally prevailing.

10 The actual fractionation takes place in a packed column containing low-pressure-loss internals. Suitable internals are, for example, arranged sheet-metal packings. Other examples can be found in **RÖMPP Chemie Lexikon, Thieme Verlag, Stuttgart, 9th Edition, Vol. 3,**

15 **p. 2305 (1990)** under the heading "Kolonnen-Einbauten" [Column internals] and in the literature cited therein. The required fine vacuum of 1 to 20 mbar at the top of the column can be achieved, for example, using water-ring pumps and upstream steam jets. The pressure drop

20 over the entire distillation unit should preferably be no more than 20 mbar. A distillate containing predominantly saturated C₁₆ portions and a bottom product containing predominantly unsaturated C₁₆-C₁₈ portions are obtained in the process. The weight ratio

25 of distillate to bottom product is in the range from 30:70 to 35:65.

Hydrogenation

 The subsequent hydrogenation of the predominantly unsaturated methyl ester fraction

30 obtained as bottom product with retention of the double bonds can be carried out in a manner known per se, i.e. for example in the presence of commercially available zinc/chromium catalysts, at temperatures in the range from 250 to 350°C and a hydrogen pressure of from 200

35 to 275 bar. The conjuene content of the products is in the range from 6 to 12% by weight, and the content of hydrocarbons is below 3% by weight, preferably below 1% by weight.

Industrial applicability

The unsaturated palm oil fatty alcohols obtained by the process according to the invention are low in color and odor and have a particularly advantageous low-temperature behavior. They are therefore suitable as raw materials for the preparation of washing, rinsing and cleaning products, and also products for hair care and body care, in which they can be present in amounts of from 1 to 50% by weight, preferably 5 to 30% by weight, based on the compositions.

Example

A technical-grade palm oil fatty acid methyl ester was fractionated in a packed column containing low-pressure-loss internals at a still temperature of 200°C and a head vacuum of 20 mbar, 30% by weight of palmitic acid methyl ester being produced as distillate, while in the still 70% by weight of a C_{16/18} fatty acid methyl ester mixture remained, which had an iodine number of 74. The ester mixture from the still was transferred to an autoclave and reduced therein in the presence of commercially available zinc/chromium catalysts at 300°C and 250 bar with hydrogen to give the mixture of the corresponding alcohols. The hydrogenation product freed from methanol had, according to gas-chromatographic and wet-chemical analysis, the following characteristics:

Table 1:

Characteristics for the hydrogenation product

Composition	Portion [area %]	Specification	Value
Cetyl alcohol	18.3	Iodine number	74
Palmoleyl alcohol	0.5	Hydroxyl number	212
Margarinyl alcohol	0.6	Acid number	0.02
Stearyl alcohol	8.5	Saponification number	0.4
Oleyl alcohol	61.2	Hazen color number	10
Linolyl alcohol	3.3	Conjuene content	6.6% by wt.
Linolenyl alcohol	6.7	Solidification point	22.7°C
Hydrocarbons	0.9
